Model Fitting / Training Process

- 1. Choose a **hypothesis set of models** to train (e.g. linear regression with 4 predictor variables)
- 2. Identify a **cost function** to measure the model fit to the training data (e.g. mean square error)
- 3. Optimize model parameters to minimize cost (e.g. closed form solution using the normal equations for OLS)

How can we...

define what makes a model linear?

fit our model to our training data?

What makes a model linear?

Which of the following models are linear?

A
$$y=w_0$$

$$y = w_0 + w_1 x_1$$

c
$$y = w_0 + w_1 x_1 + x_2^{w_2}$$

$$y = w_0 + w_1 x_1^2 + w_2 x_2^{0.4}$$

$$y = w_0 + w_1 \int \sqrt[3]{x_1} dx_1 + w_2 g(x_2) + w_3 median(x_1, x_2, x_3)$$

Model parameters are w_i Target variable is y

Remaining components are features

Which of the following models are linear?

A
$$y = w_0$$

B
$$y = w_0 + w_1 x_1$$

$$y = w_0 + w_1 x_1 + x_2^{w_2}$$

$$y = w_0 + w_1 x_1^2 + w_2 x_2^{0.4}$$

$$y = w_0 + w_1 \int \sqrt[3]{x_1} dx_1 + w_2 g(x_2) + w_3 median(x_1, x_2, x_3)$$

Model parameters are w_i Target variable is yRemaining components are features

ALL except C are linear in the **parameters**, *w*

We can rewrite these models in terms of transformed features

It becomes clear this is a linear model when we rewrite the features:

$$y = w_0 + w_1 z_1 + w_2 z_2 + w_3 z_3$$

Transformed features:

$$z_1 = \int \sqrt[3]{x_1} dx_1$$
 $z_2 = g(x_2)$

$$z_2 = median(x_1, x_2, x_3)$$

$$y = w_0 + w_1 \int \sqrt[3]{x_1} dx_1 + w_2 g(x_2) + w_3 median(x_1, x_2, x_3)$$

Linear models are linear in the parameters

A linear combination is quantity where a set of terms are added together, each multiplied by a constant (parameter) and adding the results

Linear regression model

$$y_i = \sum_{j=0}^p w_j x_{i,j} = \mathbf{w}^\mathsf{T} \mathbf{x}$$

Parameters
$$w_j$$
Target y_i
Features $x_{i,j}$
Sample Feature

$$y_i = w_0 x_{i,0} + w_1 x_{i,1} + w_2 x_{i,2} + \dots + w_p x_{i,p}$$

Intercept/bias term: $x_{i,0} = 1$

$$y_i = w_0 + w_1 x_{i,1} + w_2 x_{i,2} + \dots + w_p x_{i,p}$$

Linear regression model

$$\mathbf{y}_i = \sum_{j=0}^p \mathbf{w}_j \mathbf{x}_{i,j} = \mathbf{w}^\mathsf{T} \mathbf{x}$$

Parameters
$$W_j$$
Target Y_i
Features $X_{i,j}$
Sample Feature

$$y_i = w_0 x_{i,0} + w_1 x_{i,1} + w_2 x_{i,2} + \dots + w_p x_{i,p}$$

Intercept/bias term: $x_{i,0} = 1$

$$y_i = w_0 + w_1 x_{i,1} + w_2 x_{i,2} + \dots + w_p x_{i,p}$$

Notation

Number of features

Feature Sample

Number of samples

1	
'	

 $x_{i,j}$

Shorthand

Shorthand

$$\boldsymbol{x}_i = \begin{bmatrix} x_{i,0} \\ x_{i,1} \\ \vdots \\ x_{i,p} \end{bmatrix}$$

$$\frac{P}{\parallel}$$

Assume
$$x_{i,0} = 1$$

$$x_i = \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_p \end{bmatrix} = \begin{bmatrix} 1 \\ x_1 \\ \vdots \\ x_p \end{bmatrix}$$

Shorthand

$$N \qquad x = \begin{bmatrix} x_{1,j} \\ x_{2,j} \\ \vdots \\ x_{N,j} \end{bmatrix}$$

$$\boldsymbol{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix}$$

$$\boldsymbol{x} = \begin{bmatrix} x_{1,j} \\ x_{2,j} \\ \vdots \\ x_{N,j} \end{bmatrix} \qquad \boldsymbol{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix} \qquad \boldsymbol{X} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} x_{1,0} & x_{1,1} & \dots & x_{1,p} \\ x_{2,0} & x_{2,1} & \dots & x_{2,p} \\ \vdots & \vdots & \ddots & \vdots \\ x_{N,0} & x_{N,1} & \dots & x_{N,p} \end{bmatrix}$$

Types of Linear Regression

	One feature variable	Two or more feature variables
One target variable	Simple Linear Regression $y_i = w_0 + w_1 x_{i,1}$	Multiple Linear Regression $y_i = \sum_{j=0}^p w_j x_{i,j} \text{ or } y_i = \mathbf{w}^T \mathbf{x}_i$

Two or more target variables

Multivariate (Multiple) Linear Regression

q = # target variables
$$[1 \times q]$$

$$y_i = x_i W$$

$$[1 \times p] [p \times q]$$

$$p = # features$$

Linear models: pros and cons

Pros

Simple to implement and interpret

Excels if the relationship between features and targets is linear or can be expressed in terms of linear combinations of transformed features

Cons

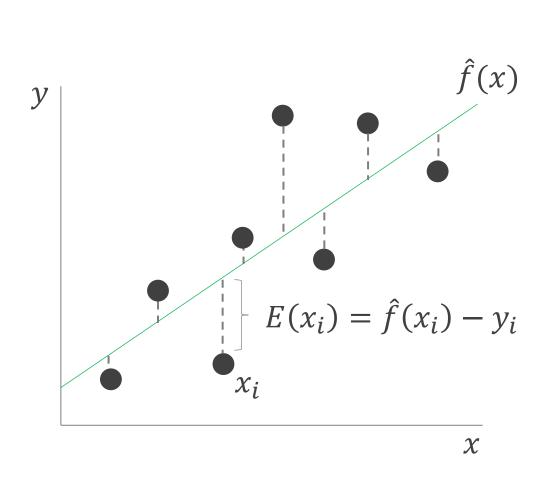

For many applications with complex feature-target relationships, underfits

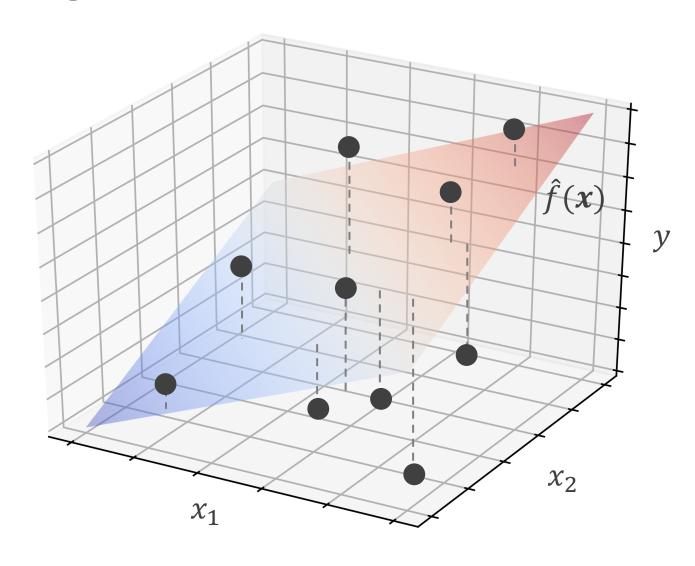

Requires feature engineering for capturing more complex feature-target relationships

How do we fit the model to the training data?

A winding path to the least squares solution

Linear models and error

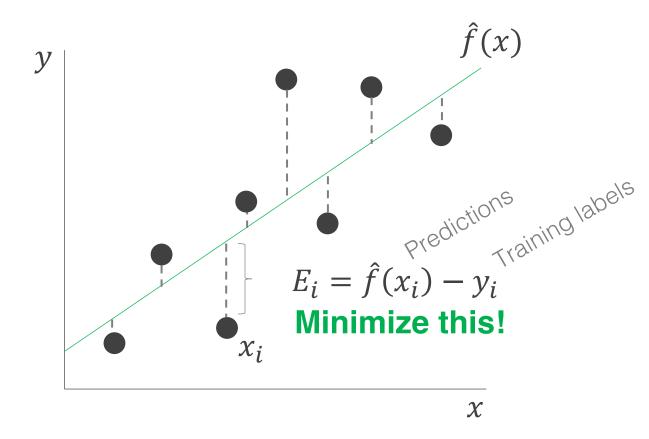

simple linear regression

multiple linear regression

How do we fit a linear model to training data?

We want the error between our predictions and training data to be small

Training data: $D = \{(x_1, y_1), (x_2, y_2), ..., (x_N, y_N)\}$

How do we measure error?

The error for one sample is:

$$E_i = \hat{f}(x_i) - y_i$$
 $\hat{y}_i = \hat{f}(x_i) = \sum_{i=0}^{p} w_i x_{i,j}$

We want to minimize the error across all our training data, so... we use mean squared error to quantify training (in-sample) error:

Training (in-sample) error:
$$E_{in}(\hat{f}, D) = \frac{1}{N} \sum_{n=1}^{N} (\hat{f}(x_n) - y_n)^2$$

We call this our **Cost Function** (a.k.a. loss, error, or objective)

Cost Function:
$$C(\hat{f}, D) = E_{in}(\hat{f}, D) = \frac{1}{N} \sum_{n=1}^{N} (\hat{f}(x_n) - y_n)^2$$

Training error is a function of our **model** and the **training data**

We can't change the data; we adjust our model to minimize cost

To adjust the model, we choose model parameters that minimize cost

This is an optimization problem

How to fit our model to the training data?

Equivalently: how do we choose \mathbf{w} to minimize cost (error)

$$E_{in}(\hat{f}, D) = \frac{1}{N} \sum_{n=1}^{N} (\hat{f}(\mathbf{x}_n) - y_n)^2$$

where
$$\hat{f}(\mathbf{x}_n) = \mathbf{w}^T \mathbf{x}_n$$

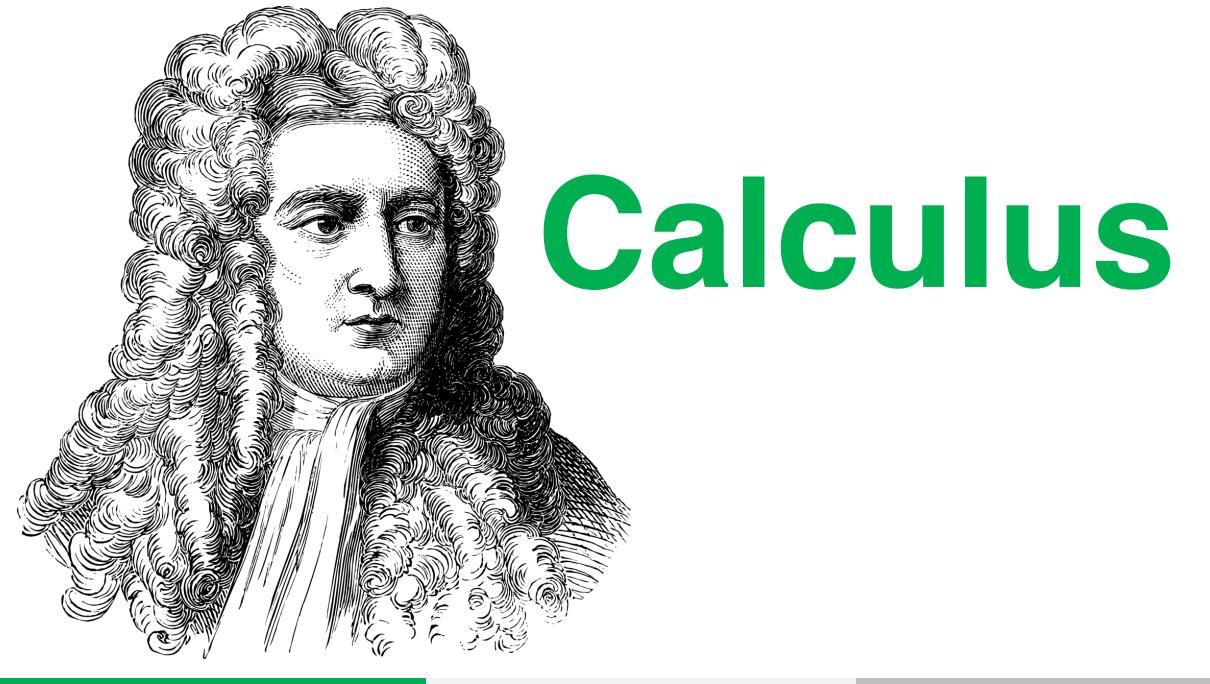

We want to minimize

...by varying w

How do we do that?

$$E_{in}(\mathbf{w}) = \frac{1}{N} \sum_{n=1}^{N} (\mathbf{w}^T \mathbf{x}_n - y_n)^2$$
Once we've determined

Once we've determined the form of the model and the training data, the model parameters **w** are the only parts we can adjust

A moment of calculus

Function of one variable

$$f(x) = ax + bx^2$$

Function of multiple variables

$$f(x_1, x_2) = ax_1 + bx_2$$

Derivative

$$\frac{df}{dx} = a + 2bx$$

Partial Derivative

$$\frac{\partial f}{\partial x_1} = a$$

$$\frac{\partial f}{\partial x_2} = b$$

Gradient

$$\nabla_{x} f = \begin{bmatrix} \frac{\partial f}{\partial x_{1}} \\ \frac{\partial f}{\partial x_{2}} \end{bmatrix}$$

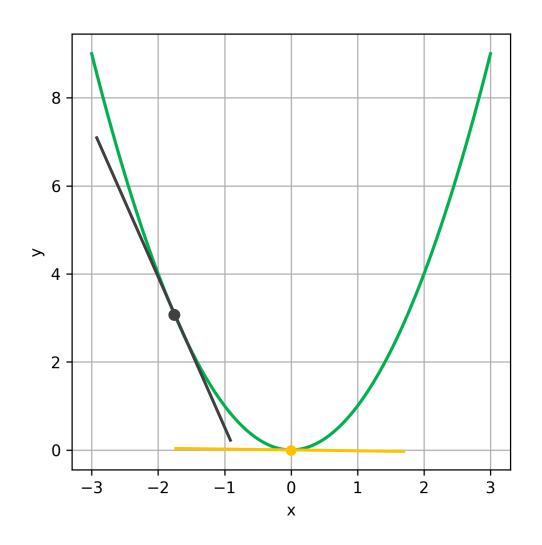

May also treat parameters as variables
$$\frac{\partial f}{\partial b} = x_2$$
 and take their partial derivative

$$=\begin{bmatrix} a \\ b \end{bmatrix}$$

Why set the derivative to 0?

Remember the derivative (and gradient) is the direction and rate of fastest increase

For a continuous, convex function, the function is minimized when that value is zero

How to fit our model to the training data?

Take the gradient with respect to w, set it to zero, and solve for w(think derivative)

$$abla_w E_{in}(w) =
abla_w \left(\frac{1}{N} \sum_{n=1}^N (w^T x_n - y_n)^2 \right)$$
 $p = \text{number of predictors}$
 $N = \text{number of data points}$

$$abla_{w}E_{in}(\mathbf{w}) = \begin{bmatrix} \frac{\partial E_{in}}{\partial w_{0}} \\ \frac{\partial E_{in}}{\partial w_{1}} \\ \vdots \\ \frac{\partial E_{in}}{\partial w_{p}} \end{bmatrix} = \mathbf{0}$$
Kyle Bradbury

Linear models

We will walk through the ordinary least squares (OLS) closed-form solution.

We could have used another optimization approach like gradient descent

Kyle Bradbury Duke University I Lecture 04

How to fit our model to the training data?

Our cost function...

$$E_{in}(\mathbf{w}) = \frac{1}{N} \sum_{n=1}^{N} (\mathbf{w}^{T} \mathbf{x}_{n} - \mathbf{y}_{n})^{2}$$

$$\mathbf{w}^{T} \in \mathbb{R}^{1 \times p + 1}$$
Scalar
$$\mathbf{x}_{n} \in \mathbb{R}^{p + 1 \times 1}$$

...can be rewritten as:

$$E_{in}(\mathbf{w}) = \frac{1}{N} (\mathbf{X}\mathbf{w} - \mathbf{y})^T (\mathbf{X}\mathbf{w} - \mathbf{y})$$

Convenient definitions:

$$\mathbf{y} \in \mathbb{R}^{N \times 1}$$

$$\mathbf{X} = \begin{bmatrix} \mathbf{x}_{1}^{T} \\ \mathbf{x}_{2}^{T} \\ \vdots \\ \mathbf{x}_{N}^{T} \end{bmatrix} \in \mathbb{R}^{N \times p+1}$$

$$\mathbf{w} = \begin{bmatrix} \mathbf{w}_{0} \\ \mathbf{w}_{1} \\ \vdots \\ \mathbf{w}_{p} \end{bmatrix} \in \mathbb{R}^{p+1 \times 1}$$

p = number of predictors N = number of data points

Kyle Bradbury Duke University I Lecture 04

Assume
$$p = 2$$
 $N = 4$

$$\mathbf{w} = \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$$

$$\mathbf{w} = \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix} \qquad \mathbf{x}_i = \begin{bmatrix} x_{i,0} \\ x_{i,1} \\ x_{i,2} \end{bmatrix}$$

p = number of predictors N = number of data points

$$m{X} = egin{bmatrix} m{x}_1^T \ m{x}_2^T \ m{x}_3^T \ m{x}_1^T \end{bmatrix} = egin{bmatrix} m{x}_{1,0} & m{x}_{1,1} & m{x}_{1,2} \ m{x}_{2,0} & m{x}_{2,1} & m{x}_{2,2} \ m{x}_{3,0} & m{x}_{3,1} & m{x}_{3,2} \ m{x}_{4,0} & m{x}_{4,1} & m{x}_{4,2} \end{bmatrix}$$

Aside on algebraic manipulations

$$Xw = \begin{bmatrix} x_{1,0} & x_{1,1} & x_{1,2} \\ x_{2,0} & x_{2,1} & x_{2,2} \\ x_{3,0} & x_{3,1} & x_{3,2} \\ x_{4,0} & x_{4,1} & x_{4,2} \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} w^T x_1 \\ w^T x_2 \\ w^T x_3 \\ w^T x_4 \end{bmatrix}$$

$$\begin{bmatrix} \mathbf{w}_0 \\ \mathbf{w}_1 \\ \mathbf{w}_2 \end{bmatrix} = \begin{bmatrix} \mathbf{w}^T \mathbf{x}_1 \\ \mathbf{w}^T \mathbf{x}_2 \\ \mathbf{w}^T \mathbf{x}_3 \\ \mathbf{w}^T \mathbf{x}_4 \end{bmatrix}$$

$$Xw = \begin{bmatrix} x_{1,0} & x_{1,1} & x_{1,2} \\ x_{2,0} & x_{2,1} & x_{2,2} \\ x_{3,0} & x_{3,1} & x_{3,2} \\ x_{4,0} & x_{4,1} & x_{4,2} \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} \mathbf{w}^T \mathbf{x}_1 \\ \mathbf{w}^T \mathbf{x}_2 \\ \mathbf{w}^T \mathbf{x}_3 \\ \mathbf{w}^T \mathbf{x}_4 \end{bmatrix}$$

$$(\boldsymbol{X}\boldsymbol{w})^T(\boldsymbol{X}\boldsymbol{w}) = [\boldsymbol{w}^T\boldsymbol{x}_1 \quad \boldsymbol{w}^T\boldsymbol{x}_2 \quad \boldsymbol{w}^T\boldsymbol{x}_3 \quad \boldsymbol{w}^T\boldsymbol{x}_4] \begin{bmatrix} \boldsymbol{w}^T\boldsymbol{x}_1 \\ \boldsymbol{w}^T\boldsymbol{x}_2 \\ \boldsymbol{w}^T\boldsymbol{x}_3 \\ \boldsymbol{w}^T\boldsymbol{x}_4 \end{bmatrix}$$

$$=\sum_{n=1}^{N}(\mathbf{w}^{T}\mathbf{x}_{n})^{2}$$

Aside on algebraic manipulations

How to fit our model to the training data?

Our cost function...

$$E_{in}(\mathbf{w}) = \frac{1}{N} \sum_{n=1}^{N} (\mathbf{w}^{T} \mathbf{x}_{n} - \mathbf{y}_{n})^{2}$$

$$\mathbf{x}_{n} \in \mathbb{R}^{1 \times p+1}$$
Scalar
$$\mathbf{x}_{n} \in \mathbb{R}^{p+1 \times 1}$$

...can be rewritten as:

$$E_{in}(\mathbf{w}) = \frac{1}{N} (\mathbf{X}\mathbf{w} - \mathbf{y})^T (\mathbf{X}\mathbf{w} - \mathbf{y})$$

Convenient definitions:

$$\mathbf{y} \in \mathbb{R}^{N \times 1}$$

$$\mathbf{X} = \begin{bmatrix} \mathbf{x}_{1}^{T} \\ \mathbf{x}_{2}^{T} \\ \vdots \\ \mathbf{x}_{N}^{T} \end{bmatrix} \in \mathbb{R}^{N \times p+1}$$

$$\mathbf{w} = \begin{bmatrix} \mathbf{w}_{0} \\ \mathbf{w}_{1} \\ \vdots \\ \mathbf{w}_{p} \end{bmatrix} \in \mathbb{R}^{p+1 \times 1}$$

p = number of predictors N = number of data points

How to fit our model to the training data?

$$E_{in}(\mathbf{w}) = \frac{1}{N} (\mathbf{X}\mathbf{w} - \mathbf{y})^T (\mathbf{X}\mathbf{w} - \mathbf{y})$$
 (take gradient, set to 0)

$$\nabla_{\mathbf{w}} E_{in}(\mathbf{w}) = \frac{2}{N} (\mathbf{X}^T \mathbf{X} \mathbf{w} - \mathbf{X}^T \mathbf{y}) = \mathbf{0}$$
 (solve for \mathbf{w})

Univariate analogy:

$$f(w) = \frac{1}{N} (xw - y)^{2}$$

$$= \frac{1}{N} (x^{2}w^{2} - 2xyw + y^{2})$$

$$\frac{df(w)}{dw} = \frac{2}{N} (x^{2}w - xy)$$

$$X^TXw - X^Ty = 0$$

$$\boldsymbol{X}^T \boldsymbol{X} \boldsymbol{w} = \boldsymbol{X}^T \boldsymbol{y}$$
 (normal equation)

$$\boldsymbol{w}^* = (\boldsymbol{X}^T \boldsymbol{X})^{-1} \boldsymbol{X}^T \boldsymbol{y}$$

Pseudoinverse
$$\mathbf{X}^{\dagger} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T$$

$$\boldsymbol{w}^* = \mathbf{X}^\dagger \boldsymbol{y}$$

What is the pseudoinverse?

Features
$$\begin{bmatrix} N \times p \\ N \times p \end{bmatrix} \begin{bmatrix} N \times p \\ N \times 1 \end{bmatrix} = \begin{bmatrix} N \times 1 \\ N \times 1 \end{bmatrix}$$

$$X \qquad W = Y$$

If N = p, then there are the same number of features as samples

(# equations = # unknowns)

If N > p, then the system of equations is overdetermined: more samples than features (# equations > # unknowns)

Can't invert X!

Overdetermined systems

Example 1

Fully determined system

equations = # unknowns

$$w_1 = 2$$

$$w_2 = 1$$

Overdetermined system

equations > # unknowns

$$w_1 = 2$$

$$w_2 = 1$$

$$w_2 = 5$$

Example 2

Fully determined system

equations = # unknowns

$$2w_1 + 3w_2 = 2$$

$$6w_1 + 1w_2 = 0.63$$

Overdetermined system

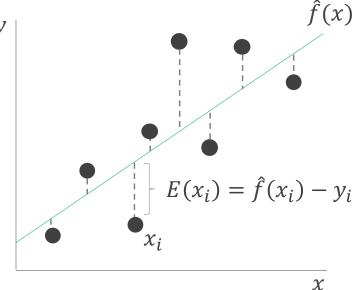

equations > # unknowns

$$2w_1 + 3w_2 = 2$$

$$6w_1 + 1w_2 = 0.63$$

$$3w_1 + 2w_2 = 14$$

$$16w_1 - w_2 = 0.1$$

What is the pseudoinverse?

Consider the case when N = 3, p = 2 (Assume no bias term here)

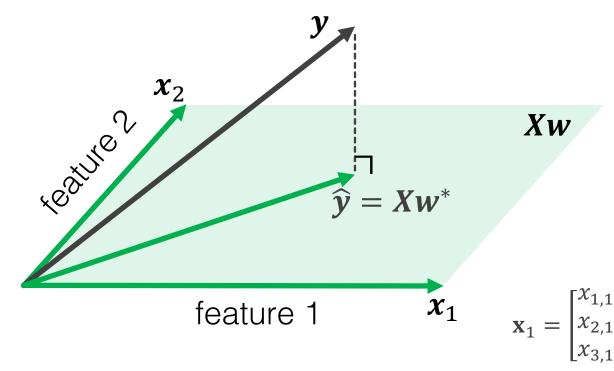

Features

X

 $w \neq y$

We CAN solve the following for w^* , the least squares solution: $x^{\dagger}w^* = v$

The least squares solution is the best we can do given N > p

Much of machine learning is optimizing a cost function

Model Fitting / Training Process

- 1. Choose a **hypothesis set of models** to train (e.g. linear regression with 4 predictor variables)
- 2. Identify a **cost function** to measure the model fit to the training data (e.g. mean square error)
- 3. Optimize model parameters to minimize cost (e.g. closed form solution using the normal equations for OLS)

We now have our model parameters, we can make predictions on unseen test data!

The parameters learned from model fitting
$$\hat{y}_i = \hat{f}(x_i) = \sum_{j=0}^p \overset{*}{w_j^*} x_{i,j}$$

Takeaways

Linear models are linear in the weights

Model fitting/training (valid beyond linear models):

- Choose a hypothesis set of models to train
- Identify a cost function
- Optimize the cost function by adjusting model parameters
